

CUTMAX EARLY

ForageMax

- Initial production for cutting, and afterwards grazing/cutting
- More species to optimize results

Optimized for early cutting

The purpose of the mixture is to cover up the need of forage in late spring/early summer when maize silage is getting short.

Production later in the season

CutMax Early offers high yields and the option for using the fields for cutting and grazing after the initial high early production.

Three different species for optimum performance

- Westerwold ryegrass for early production with high yields
- Italian ryegrass also contributing to high early yield, but with no stems in the sowing year
- Perennial ryegrass will ensure the density and persistency of the mixture if it is used in the summer and autumn

Technical Specifications

- Early and high production after spring sowing
- Transition from short term spring yield to summer/autumn production

CutMax Early

Duration: 1 year

Mixture Composition	%	Contribution of the species
Annual/westerwold ryegrass	25	To obtain the very fastest production, with stems to give some structure
Italian ryegrass	45	A stemless high quality and early production
Perennial ryegrass intermediate tetraploid	30	Production also in summer if the mixture stays in the ground
